Seafloor spreading, theory that oceanic crust forms along submarine mountain zones, known collectively as the mid-ocean ridge system, and spreads out laterally away from them. This idea played a pivotal role in the development of the theory of plate tectonics, which revolutionized geologic thought during the last quarter of the 20th century.

7. How does seafloor spreading provide evidence of past plate motion? Answers will vary. Students should change the model so that magma is pushed out of the ridge, not pulled. Students should note that the pattern is the same on both sides of the ridge. Students should note that the ocean basin forms. It will be melted to make magma.

Q. Seafloor spreading is a process that occurs at mid-ocean ridges, where new oceanic crust is formed through volcanic activity and then gradually moves away from the ridge. Q. Sea floor spreading occurs at the divergent plate boundaries. Q. Seafloor spreading is consistent at all mid-ocean ridges.

Seafloor spreading and other tectonic activity processes are the result of mantle convection. Mantle convection is the slow, churning motion of Earth's mantle. Convection currents carry heat from the lower mantle and core to the lithosphere. Convection currents also "recycle" lithospheric materials back to the mantle.

At deep-ocean trenches, subduction allows part of the ocean floor to sink back into the mantle, over tens of millions of years. The processes of subduction and sea-floor spreading can change the size and shape of the oceans. Because of these processes, the ocean floor is renewed about every 200 million years.

Significance. Seafloor spreading helps explain continental drift in the theory of plate tectonics. When oceanic plates diverge, tensional stress causes fractures to occur in the lithosphere. The motivating force for seafloor spreading ridges is tectonic plate slab pull at subduction zones, rather than magma pressure, although there is typically significant magma activity at spreading ridges.
