With bone scanning this leads to high sensitivity for focal disease if there has been any disturbance of skeletal metabolism. However. in many other clinical situations. and particularly in metabolic bone disease. more generalised alteration in skeletal turnover may occur. and quantitation of diphosphonate uptake by the skeleton can provide valuable clinical information.

BMD measurement by DXA scanning in clinical practice is an indicator of bone strength and fracture risk. There is a roughly 1.6-times increment in fracture risk for a single standard deviation decrement in bone mineral density. Results from a DXA scan are compared to reference populations defined by age, gender, and ethnicity.

Thus, the WHO diagnostic criteria for osteoporosis define osteoporosis in terms of a T-score below  $-2.5$  and osteopenia when T-score is between  $-2.5$  and  $-1$ . The T-score is calculated using the formula:  $(\text{patient's BMD} - \text{young normal mean}) / \text{SD of young normal}$ .

A bone scan is a nuclear imaging procedure. In nuclear imaging, tiny amounts of radioactive materials (tracers) are injected into a vein and taken up in varying amounts at different sites in the body. Areas of the body where cells and tissues are repairing themselves most actively take up the largest amounts of tracer.
